
**Methods and substances for the diagnosis and therapy of
sepsis and sepsis-like systemic infections**

5 The present invention relates to novel diagnostic and
therapeutic possibilities which could be derived from
novel, experimentally confirmed discoveries in connection
with the occurrence of procalcitonin or procalcitonin
partial peptides in sepsis and severe sepsis-like
10 systemic infections.

The patents DE 42 27 454 and EP 0 656 121 B1 and
US 5,639,617 disclose that the determination of the
prohormone procalcitonin and of partial peptides derived
therefrom in a serum or plasma of a patient in whom there
15 is a risk of sepsis and in whom symptoms typical of
sepsis are found is a valuable diagnostic aid for early
detection, i.e. for the detection of infections which may
lead to sepsis, and their differentiation from
noninfectious etiologies, for the detection of the
20 severity and for the assessment of the success of a
treatment of sepsis and sepsis-like systemic infections.
Said determination has proved particularly valuable for

diagnosis to distinguish symptoms attributable to systemic microbial infections from other symptoms of noninfectious etiology which, owing to their clinical picture, might suggest a sepsis but in reality are not attributable to a systemic microbial infection, for example from symptoms attributable to noninfectious inflammations of individual organs, to postoperative rejection reactions or cancers. Furthermore, systemic inflammations can be distinguished from local ones.

10 For an overview of the more recent discoveries, reference is made to W. Karzai et al. in Infection, Vol. 25 (1997), 6, pages 329-334 and the further technical literature cited or mentioned therein.

Procalcitonin became known as a prohormone of calcitonin, and its complete amino acid sequence has long been known (FEBS 167 (1984), page 93-97). Procalcitonin is produced under normal conditions in the C cells of the thyroid gland and then specifically cleaved into the hormone calcitonin and the further partial peptides katacalcin and an N-terminal residue comprising 57 amino acids ("aminoprocaltitonin").

Since in the case of sepsis greatly elevated procalcitonin levels are observed even in patients from whom the thyroid gland was completely removed, it was necessary to conclude that the procalcitonin detectable in the blood of sepsis patients is formed outside the thyroid gland, different opinions having been expressed in the technical literature, some of them supported by experimental material, with regard to the organs or cells or the tissues which are critical for procalcitonin production during sepsis.

Regarding the nature of the peptide determined as "procalcitonin" in sepsis, it was in fact made clear from

complete procalcitonin 1-116 comprising 116 amino acids but procalcitonin shortened at the amino terminus by a dipeptide but otherwise identical and having an amino acid sequence of only 114 amino acids (procalcitonin 3-116).

The dipeptide missing in comparison with the complete procalcitonin has the structure Ala-Pro. The lack of a dipeptide comprising a proline residue as a second amino acid of the amino terminus of the complete procalcitonin sequence led to the presumption that a specific peptidase might play a role in the production of the procalcitonin 3-116 detectable in the case of sepsis, that is to say the so-called dipeptidyl-(amino)-peptidase IV (DP IV or DAP IV or CD26).

For the determination of a possible role of the dipeptidyl-aminopeptidase IV in association with systemic infection or with sepsis, the inventors have therefore tested experimentally whether a correlation of the physiological DAP IV concentrations with the detection of a sepsis is possible. The results obtained showed such a correlation.

The more exact results obtained furthermore led to the development of a hypothesis that the occurrence of high procalcitonin concentrations in the case of sepsis and systemic infections may not be an isolated phenomenon but that in a similar manner elevated concentrations of other prohormones might also be measurable, so that the determination of such prohormones is a possible alternative to the procalcitonin determination or is suitable for supplementing the procalcitonin determination in individual cases or further confirming it in a diagnostically significant manner.

The discovery that it is not the complete procalcitonin

the outset in the above-mentioned patients that the specific peptide need not be completely identical to the known procalcitonin peptide of full length, which is formed in the thyroid glands as a calcitonin precursor.

5 However, the question as to whether the procalcitonin formed in the case of sepsis differs from the procalcitonin formed in the thyroid glands remain unanswered to date. Possible differences were posttranslational modifications of the known

10 procalcitonin, such as glycosylations, phosphorylations or modifications of the primary structure, but also modified, shortened or lengthened amino acid sequences. Since the analytical assay methods used to date did not reveal any differences between the procalcitonin known as

15 the calcitonin precursor and the procalcitonin formed in the case of sepsis, it was provisionally generally assumed that the procalcitonin formed in the case of sepsis is identical to the calcitonin precursor and is thus a peptide having the known procalcitonin sequence of

20 116 amino acids (procalcitonin 1-116).

As revealed by the determinations in the Applicant's laboratory, explained in more detail in the experimental section of this Application, however, the procalcitonin formed in the case of sepsis differs slightly but

25 significantly from the complete procalcitonin 1-116 formed in the thyroid gland. The differences found then led to a number of scientific conclusions which could be implemented in novel diagnostic and therapeutic methods, substances usable therein and scientific approaches which

30 could be pursued.

The starting point for the invention disclosed in the present Patent Application is the surprising discovery that the procalcitonin detectable in comparatively high concentrations in the serum of patients in the case of

35 sepsis and sepsis-like systemic infection is not the

1-116 which is found in the serum of patients in the case of sepsis but a shortened procalcitonin 3-116 is finally also of potential interest for sepsis therapy. An article by Eric S. Nylen et al., Crit Care Med 1998, Vol. 26, No. 6, pages 1001-1006 describes experimental findings which indicate that the procalcitonin occurring in the case of sepsis is not only a diagnostically important marker which is formed, for example, as a metabolic waste product but appears to play an active role as a mediator in an inflammation process caused by infection, by virtue of the fact that procalcitonin can maintain and intensify inflammatory reaction. This role of procalcitonin is at present the subject of controversy, and the test results disclosed do not give a concurring picture.

The above-mentioned discovery that a procalcitonin shortened at the amino terminus by two amino acids occurs in the case of sepsis suggests that the procalcitonin which plays an active role in the case of sepsis and other inflammatory systemic infections is likely to be this shortened procalcitonin 3-116, and that studies carried out with the procalcitonin peptide of full length gave different or contradictory results, inter alia for this reason. It is well known that many physiologically active peptides are converted into their actual active form by cleavage, for example an initial elimination of a short peptide residue. A known example is angiotensin in which peptides having considerably different physiological activities are formed from the inactive angiotensinogen having 14 amino acids by successive elimination first of a tetrapeptide and then of a dipeptide and finally of an individual amino acid. The fact that relatively slight modifications of the N-terminus of the physiologically active peptide play a role in the immunological process and can lead to considerable changes in activity in the corresponding

peptides has been confirmed by a number of very recent publications, in which however no reference to septic pathological processes is made (cf. for example J Immunol 1998, Sept. 15, 161(6):2672-5; Biochemistry 1998, Sept. 8, 37(36): 12672-80; FEBS Lett 1998, July 31, 432 (1-2):73-6; J Biol Chem 1998, March 27; 273 (13):7222-7; J Exp Med 1997, Dec 1; 186(11):1865-72).

If it is assumed that procalcitonin 3-116 is actively involved in an inflammatory process and that specific molecular receptors or similar specific binders exist for this shortened procalcitonin, novel therapeutic possibilities are opened up for influencing the course of a sepsis with the use of procalcitonin 3-116 or of agonists and antagonists which interact with the receptors for the procalcitonin 3-116 and can thus influence the physiological reaction triggered by it and hence also an inflammatory process. The use of specific binders of procalcitonin 3-116, e.g. selective antibodies, is also a therapeutic approach which is opened up by the discoveries communicated herein.

Finally, that the dipeptidyl-aminopeptidase IV might play a role in the generation of procalcitonin 3-116 in the case of sepsis and systemic infections led to a further hypothesis, namely that it might also be possible to influence a sepsis or a sepsis-like inflammatory process therapeutically by influencing the activity of the dipeptidyl-aminopeptidase IV by blocking it, for example, by suitable selective binders, antibodies or similar receptor molecules.

It is the object of the present Patent Application to protect under patent law the novel technical teachings arising from the above novel discoveries and conclusions derived therefrom, to the extent that these are accessible to patent protection taking into account the

present state of knowledge.

The attached Patent Claims provisionally summarize such protectable teachings. Further protectable teachings may arise for a person skilled in the art from the complete
5 text of the present application taking into account the experimental conditions and experimental results mentioned in the experimental section and the associated explanations. Rights are expressly reserved with regard to the claiming of such teachings by additional claims.

10 Selected experimental material which backs up the novel discovery or which demonstrates the correctness of the assumptions derived therefrom is presented below with reference to several diagrams.

In the Figures:

15 Figure 1 shows the results of a procalcitonin isolation and purification by HPLC from a pooled serum of collected sera from various patients with severe sepsis;

20 Figure 2 shows the results of a mass spectroscopic analysis of those fractions of the pooled serum from Fig. 1 which have a high procalcitonin immunoreactivity;

25 Figure 3 shows the results of the determination of the enzyme activity of dipeptidyl-aminopeptidase IV in septic sera and normal sera;

30 Figure 4 shows the results of the determination of procalcitonin in septic sera and normal sera in comparison with results of the determination of a further prohormone, namely pro-gastrin-releasing peptide (proGRP), in the same sera;

Figure 5 shows the results of the determination of procalcitonin in sera of a group of 20 normal persons and, on the other hand, 20 patients suffering from sepsis;

5 Figure 6 shows the results of the determination of pro-ANF (in pg/tube) in the same groups of normal persons and patients suffering from sepsis as in Figure 5;

10 Figure 7 shows the results of the determination of Pro-ADM (in pg/tube) in the same groups of normal persons and patients suffering from sepsis as in Figure 5;

15 Figure 8 shows the results of the determination of Pro-END (in pg/tube) in the same groups of normal persons and patients suffering from sepsis as in Figure 5; and

20 Figure 9 shows the results of the determination of Pro-BNP (in pg/tube) in the same groups of normal persons and patients suffering from sepsis as in Figure 5.

EXPERIMENTAL SECTION

A. Isolation and characterization of the endogenous procalcitonin peptide from sera of septic patients

25 By mixing serum samples from different patients suffering from severe sepsis, a mixed serum having a total volume of 68 ml was prepared. The procalcitonin concentration in the pooled serum obtained was determined with the aid of a commercial procalcitonin assay (LUMitest PCT, B.R.A.H.M.S. Diagnostica) as 280 ng/ml (total amount
30 19 μ g). The pooled serum was mixed with an identical

volume of a buffer (68 ml; 10 mM EDTA, 1 mg/ml mouse-IgG, 2 mg/ml sheep-IgG, 2 mg/ml bovine IgG, 0.1 mmol leupeptin, 50 μ M Amastatin in PBS) and the procalcitonin contained in the sample was isolated and purified by affinity chromatography.

For this purpose, the total pooled sample was pumped at a flow rate of 0.5 ml/min four times in succession over an affinity column (0.5 x 1 cm, anti-calcitonin antibodies, bound to Carbolink from Pierce, procalcitonin binding capacity about 20 μ g). The column was then washed with 30 ml of PBS, and the bound peptide was eluted with the aid of 50 mM acetic acid (pH about 2.0). The column outflow was monitored continuously for absorption at 280 nm, and the protein fraction eluted by the acetic acid was collected (final volume 2.0 ml).

The material collected in this manner was purified by reversed-phase HPLC over an rpC_{18} column μ Bondapak 0.4 x 30 mm (from Waters). The flow rate was 1 ml/min, and the mobile phase and elution conditions are shown in Table 1 below.

Table 1: Elution conditions for rp-HPLC of procalcitonin

25	Mobile phase A:	5% acetonitrile 20 mM NH_4 acetate		
	Mobile phase B:	90% acetonitrile 20 mM NH_4 acetate		
30	Gradient:	0.0 min	100% A	0% B
		2.5 min	100% A	0% B
		5.0 min	89% A	11% B
		55.0 min	56% A	44% B
		60.0 min	0% A	100% B

The column outflow was measured continuously for its

absorption at 214 nm and collected in fractions of 0.25 ml. With the aid of a commercial procalcitonin assay (LUMitest PCT, B.R.A.H.M.S Diagnostica) those fractions in which a PCT immunoreactivity was detectable were determined. It was found that the main immunoreactivity was eluted in the 51st fraction as a sharp band. In addition, protein fractions having a heterogeneous composition and lower PCT immunoreactivities were obtained in fractions 39 to 49.

Figure 1 shows the PCT immunoreactivity (expressed as ng PCT/ml) determined for the individual collected fractions of the rp HPLC chromatography, superposed with a curve which shows the optical density (OD) of the eluted fractions.

All fractions which had a positive procalcitonin immunoreactivity were dried with nitrogen by gassing. Thereafter, the samples were analyzed by mass spectrometry and subjected to an N-terminal sequencing.

In the mass spectrometric analysis (MALDI-TOF method), the profile shown in Figure 2 was obtained for fractions 50-52, from which profile a molar mass of 12640 ± 15 resulted. All other fractions (36-49, 53-59) investigated by mass spectrometry showed heterogeneous mass distributions with molar masses <12640 . Their individual mass gave an intensity of $<2\%$ in comparison with the intensity of the mass of the fractions 50-52. It was thus demonstrated that the procalcitonin immunoreactivity in sera of patients suffering from sepsis is associated with a mass of 12640 ± 15 . None of the fractions obtained had a higher mass.

The peptides contained in fractions 36-59 were subjected to an N-terminal sequencing. Here too, the content of fractions 36-49 and 53-59 proved to be heterogeneous,

i.e. a multiplicity of N-termini was determined.

For the fractions 50-52, in which the predominant procalcitonin immunoreactivity was to be found, it emerged that the peptides contained therein clearly have
5 the following N-terminus (15 amino acids):

Phe Arg Ser Ala Leu Glu Ser Ser Pro Ala Asp Pro Ala Thr Leu

The peptide from fractions 50-52 was then digested by means of protease Glu-C or trypsin, and the resulting fragments were recovered in a manner known per se by
10 means of SMART-HPLC and then investigated by mass spectrometry and sequence analysis.

A sequence which corresponded completely with the sequence of the amino acids 3-116 of the known procalcitonin 1-116 was obtained. The theoretical mass
15 of the sequence was 12627, which is in agreement with the mass of 12640 ± 15 determined by mass spectrometry.

Consequently, it was demonstrated that a procalcitonin peptide which comprises 114 amino acids and is to be designated as procalcitonin 3-116 circulates in the blood
20 of patients suffering from sepsis. The peptide is not changed by posttranslational modifications, such as phosphorylations or glycosylations.

The procalcitonin 3-116 has not yet been discussed to date in the scientific literature as a possible
25 endogenous procalcitonin partial peptide, and there has therefore also been no reason to date for a person skilled in the art specifically to prepare this peptide and to investigate it with regard to its properties. However, the above findings have now provided a reason
30 for the specific preparation of said procalcitonin 3-116 by genetic engineering techniques. Its preparation is

described below.

B. Cloning, expression and purification of recombinant procalcitonin 3-116

1. Cloning

5 The DNA fragments coding for procalcitonin 3-116 (abbreviated below to PCT 114) were isolated from a human thyroid cDNA pool using PCR amplification with the aid of suitable oligonucleotide primer. The desired fragment was cloned by means of conventional methods (Ausubel FM,
10 Brent R, Kingston RE, Moore DD, Seidman JG, Smith JA and Struhl K (1991), Current Protocols in Molecular Biology, John Wiley & Sons, New York), and the correct nucleotide sequence was verified by DNA sequencing and comparison with the known DNA sequence coding for procalcitonin.

15 For the expression of the cDNA coding for PCT 114, a vector was used which contains, in addition to a T7 promoter, a region which codes for the signal peptide of the so-called pelB protein. This pelB signal peptide ensures that a fusion protein formed after cloning and
20 expression is transported through the cytoplasmic membrane of the host cells used for the expression into the periplasmic space. During this transport process, the N-terminal signal peptide is simultaneously separated by a signal peptidase located on the membrane (Stader JA
25 and Silhavy TJ (1990), Engineering Escherichia coli to secrete heterologous gene products, Methods Enzymol. 185, 166-187). This procedure guarantees that the expression product found has exactly the desired sequence. In this procedure, the N-terminal methionine required in other
30 expression methods is absent.

After the cloning of the cDNA for PCT 114 into a vector of said type and transformation of E. coli with this

vector, procalcitonin 3-116 was expressed. The periplasmic fraction with the expressed procalcitonin 3-116 was isolated in a manner known per se (Neu HC and Heppel LA (1965), The release of enzymes from Escherichia coli by osmotic shock and during the formation of spheroblasts, J. Biol. Chem. 240, 3685-3692). After centrifuging (100,000 g, 30 min, 4°C) and filtration of the liquid supernatant (0.2 μ m) the filtrate obtained was separated by anion exchange chromatography. The fractions with procalcitonin immunoreactivity were combined and were purified by reversed-phase HPLC, as described in connection with the isolation of PCT 3-116 from septic sera.

All fractions with procalcitonin immunoreactivity were combined and lyophilized. As shown by checking the material by means of SDS-PAGE, the material thus obtained was at least 95% pure.

The identity of the expressed and purified peptide as procalcitonin 3-116 was confirmed by mass spectrometry and sequence analysis.

The recombinant procalcitonin 3-116 obtained is a novel recombinant peptide and can be used in this form for the preparation of immune reagents and investigated with respect to suitability as a therapeutic or with respect to its ability, in the context of the above-mentioned publication (Eric S Nylen, loc. cit.), to have prophylactic and therapeutic activity.

For the preparation of calibrators for PCT assays, the method described above for the preparation of procalcitonin 3-116 by genetic engineering was used in essentially identical form also for the preparation of the complete procalcitonin 1-116 and of procalcitonin 2-116.

C. Determination of the dipeptidyl-aminopeptidase IV (DAP IV) activity in normal human sera and sera from patients with severe sepsis

20 serum samples each from healthy normal persons and
5 from patients suffering from sepsis were investigated with respect to their dipeptidyl-aminopeptidase IV-specific enzyme activity. The DAP IV enzyme activity was measured fluorometrically in a manner known per se using Lys-Pro-4-methoxy-beta-naphthylamide. For this purpose,
10 in each case 2 μ l of the serum to be tested with 3 ml of substrate (50 μ g/ml Lys-Pro-4-methoxy-beta-naphthylamide, 50 mM Tris/HCl, pH 7.5) and the resulting fluorescence was measured continuously at an emission wavelength of
15 410 nm with excitation with light having a wavelength of 340 nm. The fluorescence signal was calibrated by means of a 4-methoxynaphthylamine solution. The enzyme activity determined in this manner is stated in nmol/min.

The results obtained are shown in Figure 3.

20 It is clear that the DAP IV enzyme activity in the sepsis sera is substantially lower than that in the sera of healthy normal persons (blood donor sera). Thus, the determination of the DAP IV enzyme activity in plasma or serum can also be used for detecting sepsis in patients sera.

25 The substantially reduced plasma concentration of DAP IV in the case of sepsis may be regarded on the one hand as evidence that DAP IV is involved in a sepsis process. On the other hand, the results indicate that it cannot be the concentration of DAP IV in the plasma that is
30 responsible for the formation of procalcitonin 3-116. Rather, the results obtained suggest the conclusion that procalcitonin 3-116 is formed by tissue- or cell-bound DAP IV, possibly intracellularly, and is liberated from

procalcitonin-producing or procalcitonin-storing cells.

The information contained in the literature to the effect that DAP IV is expressed from activated T-cells (cf. Hegen and Oravecz, Protein Reviews on the WEB; Fleischer, loc. cit.) indicates a close relationship between the expression of DAP IV and the activity state of the immune system, which, in the case of a septic systemic infection, is under extreme stress and therefore exhibits typical reactions which manifest themselves, inter alia, in greatly increased procalcitonin 3-116 formation.

Apart from the possibilities arising out of the above findings, for determining DAP IV in the course of the sepsis diagnosis, the above results may also indicate that the processes taking place in a cascade-like manner during a sepsis can be influenced therapeutically by DAP IV inhibitors, so that it might be possible to prevent or to reduce the liberation of procalcitonin 3-116 and other hormones or converted prohormones under sepsis, enabling pathological consequences for this prohormone liberation to be reduced or avoided.

D. Determination of the concentrations of prohormones other than procalcitonin in the case of sepsis

The fact that it is not the complete prohormone procalcitonin which is released in the case of sepsis, but a modified prohormone shortened by an Xaa-Pro dipeptide, led to the hypothesis that not only is procalcitonin 3-116 liberated in the case of sepsis but procalcitonin 3-116 is perhaps only one representative of a whole group of prohormones or similar peptides, for example those having immunomodulatory properties, which are liberated to a high degree and possibly in converted form in the case of sepsis.

Checking of known prohormones and of the amino acid sequences stated in the literature for these prohormones showed that in actual fact most known prohormones have at the amino terminus a dipeptide which can be defined as Xaa-Pro and which can therefore be eliminated in a sense similar to that observed in the case of procalcitonin. Specifically, dipeptides of said type are present at the amino terminus of a very large number of prohormones or immunomodulators. The following list of literature data in the form of a table gives an overview of some selected prohormones or immunomodulators, the dipeptide to be found in these at the amino terminus and their total number of amino acids.

The prohormones shown in Table 2 are examples of prohormones whose concentrations may be elevated in the case of sepsis, although the list is not to be regarded as exhaustive. In the case of the immunomodulators, elimination of a dipeptide is likely to influence the activity.

Table 2:

	Prohormone/ Immunomodulator	Dipeptide at the N-terminus	Total number of all amino acids
5	pro-Endothelin-1 (pro-END)	Ala Pro	195
	pro-Brain-natriuretic peptide (pro-BNP)	His Pro	108
10	Pro-Atrial-natriuretic peptide (pro-ANP; also pro-atrionatriuretic factor, pro-ANF)	Asn Pro	128
	pro-Leptin	Val Pro	146
	pro-Neuropeptide Y	Tyr Pro	69
	pro-Somatostatin	Ala Pro	92
15	pro-Neuropeptide YY	Thr Pro	69
	Interleukin 6	Val Pro	183
	Interleukin 10	Ser Pro	160
	pro-Gastrin-releasing peptide (proGRP)	Val Pro	115
20	pro-Opiomelanocortin	Trp Cys	241
	pro-Adrenomedullin (pro-ADM)	Ala Arg	164
	Procalcitonin (PCT)	Ala Pro	116

25 The experimental findings to date actually indicate that, in the case of a systemic infection, such as sepsis, in general prohormones and peptide immunomodulators, such as interleukins, are possibly liberated with modification by elimination of dipeptides at the amino terminus and that these possibly initiate further subsequent steps in the

30 cascade of an immune response by interaction with associated specific receptors or other binders.

Parallel with a procalcitonin determination in normal sera and sera from patients suffering from sepsis, the determination of further prohormones, which had been

chosen fairly randomly, was also carried out. These were
 (i) pro-gastrin-releasing peptide (proGRP), (ii) pro-
 atrial-natriuretic peptide (pro-ANP or pro-ANF), (iii)
 pro-adrenomedullin (pro-ADM), (iv) pro-endothelin (pro-
 5 END) and (v) pro-brain-natriuretic peptide (pro-BNP).

D.1. Determination of proGRP in sera from patients suffering from sepsis and from normal persons

An assay is commercially available for the determination
 of proGRP. In a recent publication, proGRP is described
 10 as a tumour marker in small-cell bronchial carcinoma
 (Petra Stieber et al., J Lab Med 1997, 21(6):336-344).
 The assay for the determination of proGRP is commercially
 available from the Tonen Corporation under the name
 ProGRP ELISA KITTM.

15 Using this kit and following the procedure prescribed in
 the information for use of the commercial kit, the
 measured results shown in Figure 4 were obtained.

A comparison of the values obtained for procalcitonin on
 the one hand and proGRP on the other hand shows that the
 20 distinction between normal sera and sepsis sera is
 clearer in the case of procalcitonin but that the proGRP
 concentrations are elevated in a manner substantially
 similar to those of procalcitonin.

D.2. Determination of pro-ANF, pro-ADM, pro-END and pro- 25 BNP in sera from patients suffering from sepsis and from normal persons

For the determination of the (pre)prohormones pro-ANF,
 pro-ADM, pro-END and pro-BNP, assays are commercially
 available in kit form from DRG (DRG Instruments GmbH, D-
 30 35018 Marburg, Germany) and were used for the following
 measurements in accordance with the manufacturer's

instructions.

Specifically, the following were used:

For the determination of pro-ANF, the Prepro-ANF 26-55 (human) RIA kit; for the determination of pro-ADM, the Pro-Adrenomedullin 45-92 (human) RIA kit; for the determination of pro-END, the Prepro-Endothelin 18-50 (human) RIA kit; and for the determination of Pro-BNP, the Prepro-BNP 22-46 (human) RIA kit from the above-mentioned company DRG.

10 In the sera of a group of 20 normal persons A-T and of 20 patients suffering from sepsis, the above-mentioned prohormones and, parallel to these, procalcitonin were determined. The results are summarized in Table 3 below. The data in Table 3 are also shown graphically in Figures 15 5 to 9.

The results shown show a more or less clear increase in the values for all measured prohormones in the case of patients suffering from sepsis compared with normal persons, although the distinction between normal persons and patients suffering from sepsis is most pronounced in the determination of procalcitonin.

The supplementary literature search furthermore reveals a publication in J. Endocr. (1988) 119, pages 159-165 which was concerned with characterization of pro-Opiomelanocortin (POMC)-related peptides in septic shock. The publication considers the question of increased endogenous opioid activity in septic shock and the influencing of selectivity by administration of steroids. A direct effect of an infectious process or the influencing of the measured values by antibiotics is not discussed. On the basis of the problem in said publication, there is no logical possibility of a

generalized discussion of the reported results including other prohormone peptides. It is only in view of the teaching of the present invention, disclosed herein, that said publication can be interpreted retrospectively as a further indication of a general increase in prohormones in the case of sepsis.

Testing for further prohormones is to be regarded as a routine measure in view of the results disclosed herein and, if such tests lead to positive results and the determination of such further prohormones is used for the diagnosis of sepsis, use will therefore have been made of the teaching of the present Application.
